POPULATION DISTRIBUTION BY AGE AND SEX — 2020 and 2050 / DISTRIBUTION DE LA POPULATION PAR ÂGE ET PAR SEXE — 2020 et 2050

These estimates are derived from the latest available analyses of national censuses, vital registration data, health records and surveys. Since many Pacific Island Countries and Territories (PICTs) have very small populations, estimates of fertility and mortality, particularly in the smaller countries and territories in Micronesia and Polynesia, are often presented as multi-year averages in order to provide more robust figures.

The 2020, 2030 and 2050 mid-year population estimates for Kiribati are based on the 2010 census count; for Papua New Guinea they are based on a final 2011 census count of 7,275,324; the Solomon Islands are based on an adjusted 2009 base population to address undercounts in their 2009 census. The 2019 census counts by age and sex for New Caledonia and the Solomon Islands were unavailable at the time of publication of this poster, and these projections may require revision when this data is released.

- The following indicators are shown in the summary table in this poster:
- a - The crude birth and death rates (CBR and CDR) refer to the estimated number of births and deaths per 1000 population during 2019-20. The numerical difference between the CBR and the CDR is also known as the rate of natural increase.
 - b - Average annual growth rates for the periods 2020-2030 and 2030-2050 are derived from the most recent SPC population projections.
 - c - The sex ratio is the number of males per 100 females, based on 2020 population estimates.
 - d - The median age is the age that divides a population into two numerically equal groups, i.e. half the population is younger than this age and half is older. Calculations are based on the 2020 population estimate.
 - e - The Total Fertility Rate (TFR) is the average number of children a woman would give birth to, during her lifetime if she were to pass through her childbearing years conforming to the fertility patterns of a given year or period. Most estimates shown here are derived from the latest available census, Demographic and Health Survey (DHS), or registration data.
 - f - Teenage fertility refers to the number of births per 1,000 females aged 15-19. Most estimates shown here are derived from the latest available census, DHS, or registration data.
 - g - The Infant Mortality Rate (IMR) is the number of deaths of children under one year of age in a given year (or reference period) per 1,000 live births during the same period. Most estimates shown here are derived from the latest available census, DHS, or registration data.
 - h - Life expectancy at birth refers to the average number of years that men and women can expect to live, based on the most recent national mortality information available. In some countries, modelled life table mortality experience was used in the projections process.

International migration statistics are not included in this poster since collection of these statistics (normally available through migration arrival and departure cards) still represents a challenge for most countries and territories. A useful proxy is a crude intersexual net migration rate, which is calculated by subtracting the annual rate of natural population increase (births minus deaths) from the intersexual population growth rate. Note: remember to convert the crude birth, death and migration rates from their standard representation as per thousand (‰) to percentages (%).
